# Wheastone Bridge Optimaization Using Factorial Experiments

Gavin Gray and Christos Anastasiades

## 2.Iterative Design

is defined in figure 2. A program provided could calculate 1.995 acheived in iteration 16 required R<sub>v</sub> for a given out of balance current - allowing ΔY to be calculated from the expected resistance at plus or minus ΔY was used as a measure of the accuracy of the circuit and 0.2mA. This response was used to regress a model in RS/1 which could be used to optimise the circuit.

at the edges of the range chosen in the experiments. The On each iteration the optimisation would find factors limited range chosen for the next experiment was then based on this observation. These ranges were chosen based on intuition - a percentage of the value the factor was found to be limited at.

The graph on the right shows the  $\Delta Y$  acheived on each iteration. This had to be plotted on a logarithmic scale for the higher iterations to be visible. Figure 2: Description of the design at different
